Push_swap test summary
Evaluation benchmarks — n=100 and n=500
Sizes with zero runs have not been sampled yet.
Sweep progress
A sweep tests each configured size once; it does not exhaust all permutations or certify evaluation coverage.
Averages
Winning result by input size

Session details & interpretation

Paused runs keep their move/checker results; affected solver and candidate timings are excluded from timing statistics and plots. Raw times remain in saved records.
Algorithm comparison
Per-run algorithm data
Rows contain only algorithms that actually ran. Comparisons are grouped by binary, settings and input size. Sample SD measures observed variability; CV is SD/mean; SEM is SD/sqrt(n), not a prediction interval. Quantiles use linear interpolation. Missing historical measurements are marked —. Chosen wins use the first minimum, matching solver tie-breaking. rr and rrr are shared forward/reverse rotations; rotation actions count each shared move twice. Counts describe emitted instructions, including possible no-ops. Timing covers candidate execution, excluding instrumentation output and candidate initialization; total solver time includes process launch, parsing, initialization, reporting and output. RSS is Linux process-wide peak memory at candidate completion, not memory owned by that algorithm; later rows inherit earlier peaks. Runtime is measured, asymptotic complexity is not. All candidate rows belong to runs whose winning output passed the reference checker; individual candidates are not independently checker-validated by this runner.

Executable versions

Averages include successful checks only. Resumed sessions may include different binaries; each run saves its exact input, settings, seed and generation ID.
